Abstract of EP0455616

A resilient sports floor comprising a top layer (1), which is designed to be a coherent sheet consisting of boards (2). In each board (2) recesses are provided in the shape of mutually parallel grooves (7) along the entire length of the board (2), in which grooves (7) strips (8) of a springy resilient material, e.g. a natural or synthetic rubber material or a porous, springy plastic material, are inserted. The thickness of strips (8) is larger than the depth of grooves, so that the strips project below the underside of layer (1) with their lower portion. The floor is provided with the free surface of strips (8) directly against a rigid sub-floor (9). In case of extremely high loads strips (8) will be pressed into grooves (7), so that the strips are relieved due to the fact that the floor is in direct contact with the sub-floor (9) with its underside.

Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

The present invention relates to a resilient sports floor of the kind comprising a relatively rigid upper layer, which is provided on a rigid sub-floor, e.g. a concrete support, via springy means. There are several resilient sports floors on the market. The choice of such a floor depends on the intended use (athletics), and the price which the buyer is willing to pay. The different kinds of floors may roughly be listed in three categories, i.e.:

1. Point resilient floors
2. Surface resilient floors
3. Combined structures

The point resilient floor is the less expensive one of the above kinds and comprises at least one resilient, soft layer which is glued directly onto a rigid sub-floor. This floor is characterized by the fact that a point load will only deform the floor directly beneath the load surface. The disadvantage of such a floor is that it has very high friction which may cause serious injuries to the athletes, and it has poor dampening properties.

The combined structures show very good properties, but they are, on the other hand, complicated and expensive and show a large structural height.

The present invention belongs to category 2, i.e. a surface resilient floor. As mentioned above, such a floor comprises a relatively rigid upper layer, which is, via resilient means, mounted onto a rigid sub-floor, e.g. a concrete sole. A commonly used floor of this kind will appear from Figure 1 in the drawing. This floor comprises a relatively rigid upper layer 1 of boards glued together and resting on a rigid sub-floor by the aid of crossed joists 2, 3, which are supported by alignment blocks 4. Between joists heat or noise insulating material may be provided.

From SE Patent No. 394307 a structure is known, in which only one layer of joists is used, with joists being supported by resilient spring elements against the rigid sub-floor. The resilient spring elements consist of curved spring leaves which are provided in recesses in the lower side of the joists, so that part of the convex arch projects outside the recess. In a non-loaded state the floor, thus, rests on evenly distributed points in the shape of the curved spring leaves. When loaded, the floor will give way, and in case of a high load the spring leaves will be urged up into the recess, and the joists get in contact with the floor.

The problem with such a structure is that the floor will give way irregularly and insufficiently, its structural height will be large and the structure will be unnecessarily expensive, also it cannot take high point loads. This last problem will arise because the floor boards or the floor sheet is subjected to deflection, since the boards or sheet only rest on the joists. This may cause damage to the floor if it is used for other activities than athletics, e.g. for exhibitions etc. High point loads may then occur due to driving with trucks, and the like. Other high point loads may occur due to movable tribunes, and the like.

It is an object of the present invention to provide a sports floor which will give way evenly and sufficiently, has a small structural height, is inexpensive, can take high point loads, and may be laid in a simple and inexpensive manner. According to the invention this is achieved by the aid of a resilient sports floor of the kind comprising an upper layer, which is designed to be a coherent sheet, consisting of boards, preferably laminated parquet boards, which rest on a rigid sub-floor, e.g. a concrete sole, by the aid of resilient means which means are provided in recesses in the underside of the sports floor. Said resilient means are intended to be urged into the recesses under the application of high loads to the floor, so that as the underside of the floor makes contact with the sub-floor the springy means are confined to the recesses and the deformation of the floor will be limited by the floor to sub-floor contact. The floor is characterized by the fact that in each board of the top layer there are recesses in the shape of mutually parallel grooves in the entire length of the board, in which grooves strips of a resilient material, e.g. of natural or synthetic rubber or a porous, springy plastic material, with a larger thickness than the depth of the recesses, are inserted, so that the lower portion of the strips projects below the underside of the layer, and that the free surface of the strips is provided directly against the rigid sub-floor.

By the aid of the invention good springiness and a long life of the floor is achieved. This is due to the fact that only a limited area of the resilient material is pressed down at a given load. Another essential advantage is that the resilient material is protected against excessive loads because the strips of resilient material will be pressed into the grooves and the rigid layer will then rest with its underside against the sub-floor. Consequently, there is a controlled compression of the resilient material, e.g. 50%. The floor can, thus, take very high loads from lift-trucks, cars, transportable tribunes, and the like without the resilient material being excessively loaded and receiving lasting damage.

Certain athletic activities are especially demanding as regards a resilient sports floor. This may, e.g. be the case with light athletics. A common resilient sports floor may then appear to be too rigid, since an athlete reaching the floor with relatively stiff legs, may bring the floor into contact with the sub-floor due to complete compression of the resilient strips. This problem is solved by the aid of the features appearing from claim 2.

Further features of the invention will appear from the dependent claims from 2 to 4.

Experiments showed that the following advantages are achieved by the aid of the floor according to the invention:

1. It gives way evenly
2. It gives way in an advantageously adapted manner
3. Its structural height is low
4. It is inexpensive
5. It can take high loads
6. Laying is easy.

If lamellar parquet is used in the relatively rigid top layer, special advantages are achieved by the invention. The parquet has very good properties as regards usage and laying is easy. The product is completely prefabricated, it is very stable as regards dimensions, and it can be laid in a resilient manner on a pre-screeded floor. Another essential advantage is that in case of renovation of an existing floor it is possible to lay the floor according to the invention on the existing floor, provided that the latter is plane. Its low structural height ensures that transition regions to doors, and the like are problem-free.

It is also possible to choose a point-resilient floor, which is very suitable for athletics, e.g. in a sports hall and to lay a floor according to the invention, consisting of manageable elements of, e.g. 1-2 m², e.g. for ball games or other activities where demands for the floor to give way are high.

- The invention will be disclosed in more detail below with reference to the drawing, in which
- Figure 1 as mentioned above, shows a known embodiment of a surface-resilient sports floor,
 - Figure 2 shows a section of an embodiment of a floor according to the invention in a non-loaded state, and
 - Figure 3 shows the floor of Figure 2, but in a loaded state,
 - Figure 4 shows a modification of the floor according to the invention in a non-loaded state,
 - Figure 5 shows the floor of Figure 4 in a slightly loaded or normally loaded state, and
 - Figure 6 shows the floor according to Figures 4 and 5 in a highly loaded state.

The relatively rigid top layer 1 of the floor consists of a lamellar parquet comprising glued together lamellar parquet blocks or boards 2. The boards are connected by a tongue and groove connection 3, both on the longitudinal and the short sides. The lamellar parquet consists of a top layer 4 of hardwood, e.g. oak, a bottom layer 5 of a less expensive wood, e.g. white-wood, extending in the same direction as does the top layer, and an intermediate blocking layer 6, which also consists of a less expensive wood. This structure proved to be very well suited for sports floors. Laying these boards may be readily and rapidly done, since they are very stable as regards dimensions and may easily be joined. In the underside of the boards parallel grooves are cut in the longitudinal direction of the boards. In said grooves strips 8 of a springy resilient material, e.g. rubber or plastic is placed. The thickness of the resilient strips is approximately twice the depth of the grooves, so that the rigid sheet formed by boards 2 will lie at a distance h above the rigid sub-floor 9 in case of a non-loaded floor.

As will appear from Figure 3, the rigid top layer 1 will be urged downwards in the direction of arrow P in case of a high load, and the underlying resilient strips will be compressed and received in grooves 7, so that the underside of the parquet will lie in contact with the rigid sub-floor 9. In this manner any crushing of the resilient intermediate layer between the relatively rigid top layer and the rigid sub-floor is avoided.

As indicated in FIG. 2, there is a gap 7' between the grooves 7 and the strips (8).

In addition to the parallel grooves 7 in the longitudinal direction of the boards 2, a solution is possible with parallel grooves extending across grooves 7.

Figures 4 - 6 show a further development of the invention. In addition to strips 8 of a springy, resilient material a further resilient material 10 is provided between strips 8 in this embodiment. The extension of this material is several times that of the strips. Material 10, which may e.g. consist of a foamed plastic material, is provided to lie with its lower surface at a distance from the support 9 in case of a non-loaded floor. This may be arranged as shown in the embodiment, by having material strip 10 inserted in the underside of each parquet board 2. As will appear from Figure 4, the boards are placed at a distance h₁ from the support 9 in a non-loaded state. In case of normal use of the floor, strips 8 will be compressed, and when the boards are loaded by a force P₂ they will be urged down so that the distance from support 9 is reduced to distance h₂ in Figure 5. If the floor is subjected to an uncommonly high force P₃, strips 8 will be further compressed, and in addition the resilient material 10 will function by being compressed. In the case of Figure 6, force P₃ was so high that board 2 is pressed with its underside all the way down against support 9. In the embodiment h₁ is 3 mm. With a normal load, Figure 5, board 2 is urged 2 mm down towards the support, so that height h₂ is 1 mm. The resilient material is, thus, compressed 1 mm before the underside of the board rests on the support. In the shown embodiment material strips 8 are dimensioned to be compressed 50% when board 2 is in contact with the support 9 with

its underside. The same is also true of resilient material 10. No crushing pressure will, thus, be exerted on strips 8 or material 10.

The embodiment according to Figures 4 - 6 will solve the problems with a resilient or yielding floor which is subjected to especially high loads, e.g. in case of light athletics. If a relatively heavy, sturdy gymnast comes down on the floor with relatively stiff legs, the floor will be made to contact the support due to the resilient strips 8 being completely compressed. By the aid of the intermediate, additional resilient material 10, which lies at a certain distance from the support, progressive springiness is achieved, because the strips must be compressed at first, until the further resilient material 10 will contact the support. In stead of providing the further resilient material 10 between strips 8 approximately the same effect may be achieved by providing an entire mat of resilient material on top of the support and arranging the embodiment according to Figures 2 and 3 on top of the coating.

Claims

1. A resilient sports floor of the kind comprising a top layer (1), which is designed to be a coherent sheet, consisting of boards (2), preferably lamellar parquet boards, which rest on a rigid subfloor (9), e.g. a concrete sole, via resilient springy means which means are provided in recesses (7) in the underside of the sports floor, the springy means being intended to be urged into the recesses under the application of high loads to the floor, so that as the underside of the floor makes contact with the sub-floor the springy means are confined to the recesses and the deformation of the floor will be limited by the floor to sub-floor contact, **characterized** in that in each board (2) of the top layer (1) there are recesses in the shape of mutually parallel grooves (7) extending along the entire length of the board (2), in which grooves a natural or synthetic rubber material or a porous springy plastic material with more depth than the depth of the grooves is placed, so that the strips with their lower portions project below the underside of layer (1) and are provided with the free strip surface directly against the rigid sub-floor (9).
2. A resilient sports floor according to claim 1, **characterized** in that in grooves in the boards (2) between strips (8) a further springy material (10) is provided, which projects less far from the underside of layer (1) than strips (8).
3. A resilient sports floor according to claim 1 or 2, **characterized** in that strips (8) and the springy material (10) project below the underside of layer (1) with approximately half of their thickness.
4. A resilient sports floor according to claims 1 and 2, **characterized** in that there are two grooves (7) in each board (2).
5. A resilient sports floor according to any of claims 1 through 4, **characterized** in that there is a gap (7') between the grooves and the strips (8).

Patentansprüche

1. Federnder Sportboden der mit einer oberen Lage (1), die als eine zusammenhängende Platte ausgebildet ist, bestehend aus Brettern (2), vorzugsweise lamellaren Parkettafeln, die auf einem starren Unterboden (9), beispielsweise einer Betonsohle, mittels elastischer federnder Mittel ruhen, die in Vertiefungen (7) in der Unterseite des Sportbodens vorgesehen und dazu bestimmt sind, bei Aufbringung von hohen Belastungen auf den Boden in die Vertiefungen eingedrückt zu werden, so daß dann, wenn die Unterseite des Bodens in Berührung mit dem Unterboden gelangt, die federnden Mittel auf die Vertiefungen beschränkt sind und die Verformung des Bodens durch den Kontakt zwischen Boden und Unterboden begrenzt ist, **dadurch gekennzeichnet**, daß in jedem Brett (2) der oberen Lage (1) Vertiefungen in Form von zueinander parallelen Nuten (7) vorgesehen sind, die sich über die Gesamtlänge des Brettes (2) erstrecken, in welchen Nuten ein Natur- oder Kunstgummimaterial oder ein poriges elastisches Kunststoffmaterial mit größerer Dicke als die Tiefe der Nuten eingesetzt ist, so daß die Streifen mit ihren unteren Bereichen unterhalb der Unterseite der Lage (1) überstehen und mit der freien Streifenfläche direkt am starren Unterboden (9) angeordnet sind.
2. Federnder Sportboden nach Anspruch 1, **dadurch gekennzeichnet**, daß in Nuten in den Brettern (2) zwi-

schen Streifen (8) ein weiteres federndes Material (10) vorgesehen ist, das weniger weit als Streifen (8) über die Unterseite der Lage (1) übersteht.

- 5 3. Federnder Sportboden nach Anspruch 1 oder 2, **dadurch gekennzeichnet**, daß Streifen (8) und das federnde Material (10) mit etwa der Hälfte ihrer Dicke unterhalb der Unterseite der Lage (1) überstehen.
4. Federnder Sportboden nach den Ansprüchen 1 und 2, **dadurch gekennzeichnet**, daß zwei Nuten (7) in jedem Brett (2) vorgesehen sind.
- 10 5. Federnder Sportboden nach wenigstens einem der Ansprüche 1 bis 4, **dadurch gekennzeichnet**, daß ein Zwischenraum (7') zwischen den Nuten und den Streifen (8) vorgesehen ist.

Revendications

- 15 1. Plancher élastique de sports du type comprenant une couche de dessus (1), qui est conçue pour être une feuille cohérente, constituée de planches (2), de préférence des planches de parquet en lamelles, qui reposent sur un sous-plancher rigide (9), par exemple une dalle en béton, via des moyens élastiques faisant ressort, ces moyens étant prévus dans des évidements (7) dans le côté inférieur du plancher de sports, les moyens faisant ressort étant destinés à être sollicités dans les évidements sous l'application de charges élevées sur le plancher de sorte que, lorsque le côté inférieur du plancher vient en contact avec le sous-plancher, les moyens faisant ressort sont confinés dans les évidements, et la déformation du plancher sera limitée par le contact du plancher avec le sous-plancher, caractérisé en ce que dans chaque planche (2) de la couche de dessus (1), sont prévus des évidements sous la forme de gorges (7) mutuellement parallèles s'étendant sur toute la longueur de la planche (2), et dans ces gorges est placée une matière de caoutchouc naturel ou synthétique ou une matière plastique poreuse faisant ressort présentant une profondeur supérieure à la profondeur des gorges, de sorte que les bandes avec leurs portions inférieures, font saillie en dessous du côté inférieur de la couche (1) et sont prévues pour venir avec la surface de bande libre directement contre le sous-plancher rigide (9).
2. Plancher élastique de sports selon la revendication 1, caractérisé en ce qu'il est prévu dans les gorges dans les planches (2), entre les bandes (8), une autre matière (10) faisant ressort qui fait saillie sur une distance moins importante depuis le côté inférieur de la couche (1) que les bandes (8).
- 35 3. Plancher élastique de sports selon la revendication 1 ou 2, caractérisé en ce que les bandes (8) et la matière faisant ressort (10) font saillie en dessous du côté inférieur de la couche (1) avec approximativement la moitié de leur épaisseur.
4. Plancher élastique de sports selon les revendications 1 et 2, caractérisé en ce que deux gorges (7) se trouvent dans chaque planche (2).
5. Plancher élastique de sports selon l'une des revendications 1 à 4, caractérisé en ce qu'il y a une fente (7') entre les gorges et les bandes (8).
